

Use machine learning to predict relevant support content based on historical user interactions

PROJECT PLAN

Sddec18 -16

Client: Workiva

Advisers: Neil Zhenqiang Gong

Team Members/Roles

Erin Elsbernd: Communication coordinator and Machine Learning Lead

Ram Luitel: Project Manager and Software Architect

Faizul Jasmi: Testing and AWS Tech Lead

Taizhong Huang: QA Lead

Christian Chiang: Webmaster and AWS Tech Lead

Khoa Bui: Webmaster and DB lead

1 Introductory Material

1.1 ACKNOWLEDGEMENT

We feel very thankful and fortunate to be assigned to this project which will help us develop our machine learning skills. The success and outcome of our project require a lot of guidance and assistance from many people and we are extremely privileged to have this input.

We respect and thank Mr. Alex Kharbush for developing this project and giving ISU students the chance to tackle the problem. We are also grateful for the resources and direction he provides throughout the week. We would also like to recognize Dr. Neil Gong for being our faculty advisor and meeting biweekly to provide necessary support and guidance.

We heartily thank Dr. Joseph Zambreno for constant encouragement, support and guidance which will be helpful to us to successfully complete our project work. Also, we would like to extend our sincere esteems to all teaching assistants for their input.

1.2 PROBLEM STATEMENT

Workiva has an application called Wdesk. At the moment Wdesk users utilize a search engine to search for help articles when they have a problem with the app. However, the search bar is not the most effective at listing specific help articles based on the needs of the user. Searching for a topic requires browsing through many different articles, and then browsing through the contents of each of those articles to hopefully arrive at the solution to the user's problem.

Workiva would like to automate the help article search process by tracking the user's actions while using Wdesk and predicting a help article based on these actions. Currently there are no automated tools that suggest relevant help articles to the Wdesk user. Therefore, if a user cannot troubleshoot an issue they will often call a customer support number. With this current setup, if Workiva wants to expand their business, they will need to hire additional customer support staff to handle larger accounts. This is not a sustainable business model. Workiva would like to provide a better customer support experience with their Wdesk app, by using predictive models to help the user troubleshoot instead of humans.

1.3 OPERATING ENVIRONMENT

This will not be a stand alone application and will be dependent on the virtual environment provided by Workiva. Our application will eventually need to be part of the larger Wdesk application that Workiva clients use. The end product of this project will need to run in the cloud to simplify infrastructure management, deploy more quickly, lower cost, and give a real time solution. Our end product will be deployed in Amazon Web Service (AWS). As our application will be platform independent users can use it on any operating system where Wdesk runs.

1.4 INTENDED USERS AND INTENDED USES

This product will be used by Workiva customers as a part of the Wdesk application. It may also be used by employees developing Wdesk.

1.5 ASSUMPTIONS AND LIMITATIONS

The only cost factor for our project is Amazon Web Service licence which our client will provide us. The assumption we have is that our end product should compile and run on AWS as this is one of the requirements that our client has. If our models have over 70% prediction accuracy than Workiva would like to use our end product.

The limitations we have are technical skills among the team members. Only a few team members have machine learning experience through either classes or internships. We intend to mitigate this issue by setting aside research time for getting familiar with machine learning models and libraries. Some other limitations may include integration of our system with the Wdesk application. As Wdesk is a commercial application we might not have access to it when we are required to integrate our product with the full application. Testing limitations is another challenge as we can only test our model with the smaller datasets provided by our client.

1.6 EXPECTED END PRODUCT AND OTHER DELIVERABLES

At the end of the next semester , we should have a fully functional model that can predict a relevant help article given a user's actions using Wdesk with over 70% accuracy. We will also need to deliver all project related documents that include design, code, project architecture documents and potential documents that include instructions on how to use our models. For more detail on deliverable dates please refer to section 2.10.

2 Proposed Approach and Statement of Work

2.1 OBJECTIVE OF THE TASK

The objective of our project is to create a recommendation system that can predict the most useful article for a given user based on how they have interacted with the Wdesk app. This recommendation model should eventually run on AWS and be able to be updated daily with new data.

2.2 FUNCTIONAL REQUIREMENTS

- The recommendation system should be able to make recommendations for help articles and display the recommended article ID.
- The classification model should be optimized to run as quickly as possible.
- The classification model should be able to be updated daily given new data.

2.3 CONSTRAINTS CONSIDERATIONS

Our team has little experience with machine learning and recommendation systems so we will have to do a great amount of research and learn quickly to complete the project. Our client would like to have a feasible classification model by May 2018 so that particular deliverable will need to be completed by that time.

We will also need to work closely with our client to ensure that our system is developed in a way where it could be eventually incorporated into the Wdesk app. We also need to take into account that our team is composed of undergraduate students who are working part-time, so some of the timelines may need to be readjusted.

2.4 PREVIOUS WORK AND LITERATURE

Google, Amazon, and Facebook are also working on recommendation systems based on historical data of user behavior. Their advantages are that they have data points to detect users' behaviours and more users' data to test and train. However, their users are too complex; they have so many different groups of users who have totally different behavior patterns and knowledge background. In the other word, their data set has a lot of noise. By contrast, we clearly know our target users; Our target user share similar education background and are doing similar business work. For our project, the scope is more limited as we will be making predictions for one particular application and have a smaller set of user data to draw upon. There are many machine learning libraries available, e.g. tensorflow and scikit-learn that have models and tools to create a recommendation system.

2.5 PROPOSED DESIGN

The overall design will be a recommendation model that can predict relevant help articles based on user activity with wDesk. It will need to be able to run on AWS and update on their as well. We will need to develop an appropriate data pipeline to capture the user data, process it, and feed it to our prediction model. The specific design of the model is not yet decided as we have not tested any models with the data yet.

2.6 TECHNOLOGY CONSIDERATIONS

We are planning on using primarily open-source tools and libraries. For creating our models we will be using scikit-learn and keras. Eventually we would like to put our development environment in a Docker container so that any deprecations of future versions won't affect the model.

2.7 SAFETY CONSIDERATIONS

We need to ensure all data is anonymized so that there is no breach of privacy.

2.8 TASK APPROACH

One of the most important aspects of our project is the model to make help article recommendations. Thus, we will be spending the majority of this first semester researching and implementing different models to try out with our data. This will also involve experimenting with different ways to generate features and testing parameters for our models. We will work closely with our client with model selection and tuning based on the needs of the final product. Once we have selected a model, then we can work on creating the data pipeline and getting it and the model to work smoothly on AWS, and eventually make the model update given new data.

2.9 POSSIBLE RISKS AND RISK MANAGEMENT

Include any concerns or details that may slow or hinder your plan as it is now. These may include anything to do with costs, materials, equipment, knowledge of area, accuracy issues, etc.

There is a risk that we may not finish our project. To avoid this we need to make sure we have a realistic project plan and schedule that we follow. We need to ensure we give ourselves enough time to research and execute our tasks. We also need to make sure that if we are not getting good accuracy with our models that we reach out to the faculty advisor and client for help. There is a risk that one of the open source libraries that we use may no longer be available or supported through the year. To mitigate this we need to research several machine learning libraries for use with python so that we have alternative options if the problem arises.

2.10 PROJECT PROPOSED MILESTONES AND EVALUATION CRITERIA

Milestones	Description	Planned Date *(tentative)
Research/Get experience	1.Scikit-Learn 2.Keras with Tensorflow	2018-02-05
Experiment with Classification and Recommendation Models	1. Test out previously used recommendation algorithms and feature generation models with our data. 2. Ensure we understand how the models work.	2018-02-28
Get at least 70% accuracy on at least one model	1.Develop our own models based on the data and preexisting ones to predict help articles.	2018-03-15

Testing	1. Test algorithm and tune more as needed.	2018-03-31
Run model on AWS	1. Get model ready to deploy and run with data on AWS.	2018-04-20

2.11 PROJECT TRACKING PROCEDURES

We will use Trello to assign tasks into two week sprints. These tasks will be assigned according to team roles, what has been accomplished in the past weeks, and our goals moving ahead. We will try to split up tasks such that they can be completed within a two week time period. Our team will meet weekly both as a team and with either our client or faculty advisor to make sure we are on track with our sprints and deliverables. We will be utilizing a gantt chart to track our schedule and progress.

2.12 EXPECTED RESULTS AND VALIDATION

Research/Get experience

1. Learn how to create basic ML models with scikit-learn and Keras.

Experiment with Classification and Recommendation Models

1. Elicit input from client and faculty advisor in researching how different machine learning algorithms work and which ones we may like to prototype with our data.
2. Select different models for final prototyping and get preliminary results using our data.

Get at least 70% accuracy on at least one model

1. Continue testing and tuning models until we can get 70% accuracy on a model.
2. Elicit feedback from faculty advisor and client on how to best tune models to achieve this threshold.

Testing

1. Continue testing and tuning model as client requests.
2. Configure model to update given new data.

Run Model on AWS

1. Get model to run on AWS.
2. Test functionality of model on AWS.

2.13 TEST PLAN

3 Project Timeline, Estimated Resources, and Challenges

3.1 PROJECT TIMELINE

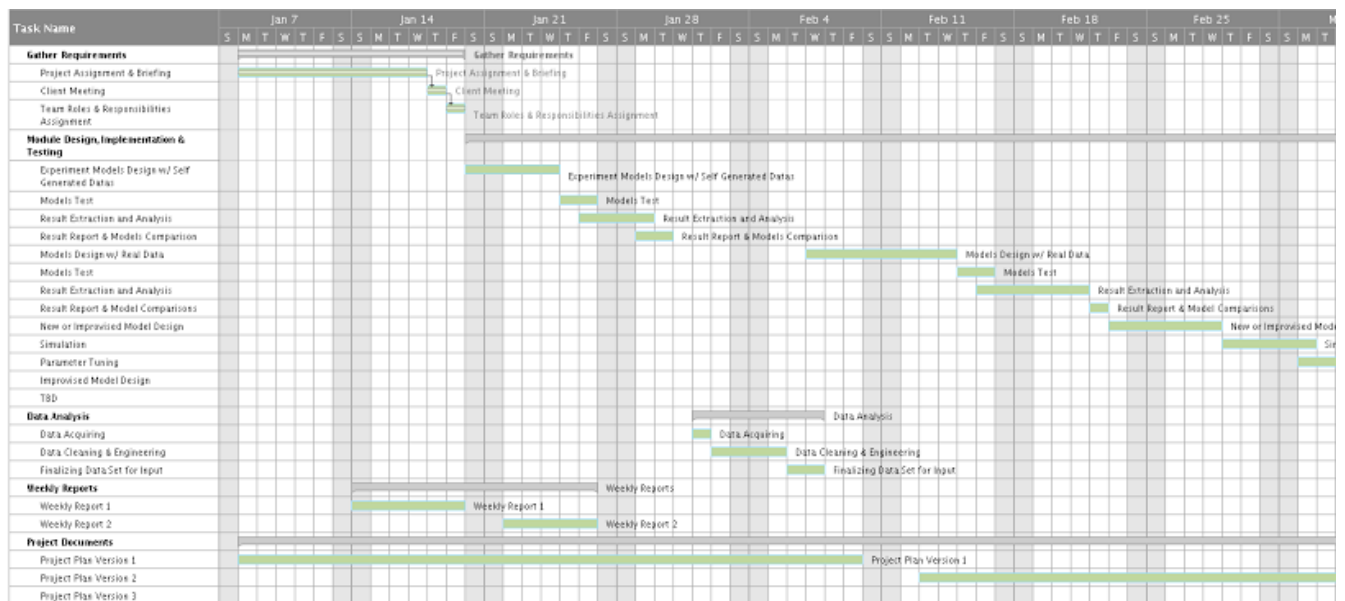

Figure 1.1: Project Timeline Part 1

Figure 1.2: Project Timeline Part 2

The given Gantt chart is modeled based on what we have planned with our team members and client so far. For development and testing, we only have planned deliverables up until March 14th. From thereafter, it is TBD. Throughout that period, our development phase from March 14th onwards would be more clear to be planned after we analyze the outcome of the deliverables that we have planned so far.

As we have received real data from the client, we are able to plan the timeline for data analyzing and implementation accurately.

For the requirements gathering phase, we have successfully followed the timeline with desirable outcomes from the deliverables.

3.2 FEASIBILITY ASSESSMENT

The team has worked together in the past in previous classes and has always completed the work assigned. We are all enthusiastic about machine learning and we got one team member who has previous internship experience using machine learning. Others in the team have also had internships in multiple companies and have a broad perspective of what it is to work in the “real world”. The project proposed by Workiva is feasible as long as we can generate good features for our models given the data. They are asking for a article suggestion model for their WDesk application depending on how the user interacts with the program. As long as we have process our data well, and carefully select our model with input from our client, we believe this project is feasible.

3.3 PERSONNEL EFFORT REQUIREMENTS

Task	Estimated Hours	Description
Research	120	The project consist of more than just machine learning. As there are many areas to focus, each team member has been assigned a specific topic: AWS, Data Management, Machine Learning and much more.
Architecture Design	350	The core fundamental of any system is its design. A good architecture will make the development of the project much easier.
Machine Learning Models	300	In this task we will focus on training our models and see how they perform, comparing the models and choose the best performing one.
Data Processing	100	Using the data provided to us by Workiva we will test which formats and features will work the best for each different model.
Testing Functionality	150	Testing will happen throughout the whole project. We will do this in sprints checking that every component works well.

3.4 OTHER RESOURCE REQUIREMENTS

- Amazon Web Services
- Datasets of User Interaction on Wdesk
 - Large training set
 - Intermediate testing set for comparisons
 - Smaller testing set

3.5 FINANCIAL REQUIREMENTS

As for now, most of the resources that we use and need are open sources materials and softwares.

Moreover, our client has not emphasized any budget or materials he would need to provide us at a cost. In the future, most resources will be provided by the client.

4 Closure Materials

4.1 CONCLUSION

Through the project, we will solely work on providing a solution to a smart customer help portal that has learning capabilities. The solution will allow customers to find the correct solution to their problem or queries without having to do much searching or browsing on WDesk app.

To achieve such goal, the plan is divided into 2 phases.

First Semester (Phase 1): In phase 1, we would first gather information and requirements from the client. The client will also give us data for us to work on and progress towards designing a model for machine learning. From thereafter, we would constantly do testing, analyzing, improving, parameter tuning and learning of the models that we have designed.

During this phase, the goal is to come up with the best possible model that generates the most accurate results.

Second Semester (Phase 2): Right now, the specifics for phase 2 is still unclear. However, the general plan for phase 2 is to have the model deployed on AWS and try to integrate it with the Wdesk application.
